Abstract

The inability to access health care services is a significant issue in the United States (US). The US Census Bureau reports that as of 2009 over 50 million individuals (16.7% of the population) lacked health insurance. The number of people who became uninsured has also increased over time. One segment of the US population that is particularly vulnerable to health care inequities is Latinos.

Failure to access timely primary medical services may increase the risk of disease transmission, morbidity, and mortality. In addition, failing to address health care needs at the primary provider level may contribute to an overutilization of potentially unnecessary emergency room services. To address health care disparities and inequalities, community partners must collaborate to provide the needed services.

This report will describe the collaboration between community health nurses and physical therapists when providing services to address the musculoskeletal health of the workers. In addition, this report will describe the service and experiential opportunities for physical therapy students including the opportunity to provide care within an interprofessional setting, practice techniques and provide service in a unique environment, and to develop aspects of professionalism.

The inability to access health care services is a significant issue in the United States (US). The US Census Bureau reports that as of 2009 over 50 million individuals (16.7% of the population) lacked health insurance (Denvas-Walt, Proctor, & Smith, 2010). This was a 2.5 million increase in uninsured individuals from the previous year (Denvas-Walt, Proctor, & Smith, 2010). One segment of the US population that is particularly vulnerable to health care inequities is Latinos (Shah & Carrasquillo, 2006). The Latino population (described by the US Census Bureau as “persons of Hispanic or Latino origin”) is the largest ethnic minority in the US accounting for nearly 16% of the US population (Denvas-Walt, Proctor, & Smith, 2010; Shah & Carrasquillo, 2006). When compared with other races and/or ethnic groups in the US, Latinos are the most likely to be uninsured with 32% of all Latinos lacking health insurance (Denvas-Walt, Proctor, & Smith, 2010; Farquhar et al., 2008; Hoerster, Beddawi, Peddeccord, & Ayala, 2010; Mueller, Patil, & Boilesen, 1998; National Center for Farmworker Health, 2011; Shah & Carrasquillo, 2006). A subset of the Latino population that is particularly vulnerable to health care disparities is undocumented immigrants (Hoerster et al., 2010; Shah & Carrasquillo, 2006). While it is difficult to ascertain exact numbers of individuals who would be classified as “undocumented,” the US Census reports 46% of all non-citizen immigrants lack health insurance (Denvas-Walt, Proctor, & Smith, 2010).

Individuals who lack health insurance are less likely to seek medical services from primary providers and/or will be more likely to present to an emergency room for their medical care (Carr, 2006; Flores & Deal, 2003; Mariger et al., 2009; National Center for Farmworker Health, n.d.a). Undocumented immigrants may not seek medical care fearing that if their immigration status is identified they will be deported (Bustamante, Fang, Rizzo, & Ortega, 2009; Marshall, Urrutia-Rojas, Soto Mas, & Coggins, 2005). From a public health perspective, the inability to access timely primary medical services may increase the risk of disease transmission, morbidity, and mortality (Kullgren, 2003). In addition, failing to address health care needs at the primary provider level may contribute to an overutilization of potentially unnecessary emergency room services (Kullgren, 2003; Pralinkas & Arciniega, 1999).

Purpose

The purpose of this report is to describe a unique, interprofessional health care program for an at-risk population (Latino migrant farmworkers) that lacks both health insurance and access to health care providers. Community health nurses in northwest Oregon collaborate with university health care providers and other health care groups to perform health screen, provide treatments, and when necessary refer migrant workers to other medical providers. This report will describe the collaboration between the community health nurses and physical therapists when providing health care services to address the musculoskeletal health of the workers. In addition, this report will describe the service and experiential opportunities for physical therapy students including the opportunity to provide care within an interprofessional setting, practice techniques and provide treatment in a unique environment, and develop aspects of professionalism (Knauss et al., 2003; Mayne & Glasscock, 2002; Sernas, O’Hare, Lehman, & Milligan, 1999).

Access to Health Care in Oregon for Latino Farmworkers

Latino account for 11% of Oregon’s population with forecasts expecting upwards of 40% growth through 2020 (Oregon Commission on Hispanic Affairs, 2010; US Census Bureau, 2011). Educational attainment is low with a vast majority of Latinos (25 years and older) either lacking a high school diploma (46.3%) or attaining a high school diploma as their highest level of education (24%) (Oregon Commission on Hispanic Affairs, 2010; Denvas-Walt, Proctor, & Smith, 2010). Over one-third (37%) of Latinos in Oregon are foreign born and are not US citizens (Oregon Commission on Hispanic Affairs, 2010). Factors such as these may impact employment opportunities for these segments of the Latino population.

One industry that does not require post-high school training for many of its positions is agriculture and farming. Agriculture and farming is a major industry in the state of Oregon, with Latinos representing the majority of all individuals involved in this occupation (National Center for Farmworker Health, n.d.a; Bureau of Labor Statistics, 2011). Oregon farms rely on the estimated 100,000 migrant and seasonal workers; however a majority (approximately 77%) of these workers are employed in only seasonal positions (Filsinger, 2004).

Migrant and seasonal farmworkers risk exposure to pesticides, musculoskeletal injury, and death in an industry that is considered to be one of the most hazardous occupations in the United States (Kato et al., 2006; Mariger et al., 2009; McCauley et al., 2005; McCauley et al., 2006; Filsinger, 2004; Zuskin, Mustajbegovic, Schachter, Kern, & Pavich, 1997). The physical demands associated with this line of work require long hours of performing repetitive tasks, often at fast speeds (Meyers et al., 2001). Meyers et al. (2001) reported 29 musculoskeletal disorders (MSD) in a population of 194 vineyard workers classified as “undocumented.” Over 400 work days were lost due to the MSDs in this population (Meyers et al., 2001). A majority of all MSDs occurred in the back (69%) with the remaining MSDs experienced equally amongst the neck/shoulder, hand/arm, and the lower extremities (Meyers et al., 2001). Brumitt et al. (2011) reported similar findings in a population of Latino migrant/seasonal vineyard workers. Forty-five percent of all males and 75% of all females described experiencing musculoskeletal symptoms (MSS) in one or more regions of their body (Brumitt et al., 2011). The workers reported the back (thoracic and lumbar spine) as the primary region where they experienced MSS (Brumitt et al., 2011). Of the 115 males that reported MSS, 82 (71.3% of all males with MSS complaints or 32% of the entire male sample population) were experiencing MSS in the back (Brumitt et al., 2011). Twenty-four of 32 female workers reported MSS with 14 female workers (58.8% of all females with MSS complaints or 43.7% of the entire female sample population) were experiencing MSS in the back (Brumitt et al., 2011).

The ¡Salud! Program and Interprofessional Collaboration

Collaboration

To address the health care needs of some migrant vineyard workers in Oregon, winemakers in the Willamette Valley (northwest Oregon) and physicians in Washington County (Oregon) created the ¡Salud! program (Salud!, 2011). For nearly two decades the ¡Salud! program has increased health care access for migrant workers and their families (Salud!, n.d.). Health care providers from the ¡Salud! team (Tuality Health Care, Hillsboro, Oregon), and assisted by community partners and volunteer health care professionals from Pacific University (Hillsboro, Oregon) provide on-site health screening clinics every year at vineyards during the spring and summer months. Services provided at these clinics include health care screening (cholesterol, blood pressure, height, weight, body mass index), nurse practitioner examinations (University of Portland), vaccinations, musculoskeletal examinations (performed by Pacific University faculty and student physical therapists), optometric examinations (Pacific University Faculty of Optometry, 2012). Despite the aforementioned risks associated with agricultural work, migrant farmworkers generally lack access to health care services (over two-thirds of all farm workers lack health insurance) (Carr, 2006; Farquhar et al., 2008; Filsinger, 2004; McCauley et al., 2006; National Center for Farmworker Health, n.d.b; Sherrill et al., 2005; Zuskin et al., 1997). If a migrant farmworker becomes sick or injured, he or she may face several barriers to accessing health care (Bustamante et al., 2009; Hoerster et al., 2010; Kullgren, 2003; Marshall et al., 2005; McCauley, 2005). For those who lack health insurance, the out-of-pocket costs are prohibitive. With low health care groups to perform health screens, provide treatments, and when necessary refer migrant workers to other medical providers. This report will describe the collaboration between the community health nurses and physical therapists when providing health care services to address the musculoskeletal health of the workers. In addition, this report will describe the service and experiential opportunities for physical therapy students including the opportunity to provide care within an interprofessional setting, practice techniques and provide treatment in a unique environment, and develop aspects of professionalism (Knauss et al., 2003; Mayne & Glasscock, 2002; Sernas, O’Hare, Lehman, & Milligan, 1999).
University), dental health services (Pacific University), mental health services, and health education (Brumitt et al., 2011; Reynolds, 2009).

Vineyard workers are encouraged to participate with clinics scheduled during regular working hours. At the start of each clinic, workers complete the ¡Salud! health intake form and the ¡Salud! medical ID card paperwork. The ¡Salud! medical ID card increases one’s ability to access local medical care with services provided at a reduced rate. Once the paperwork is completed, workers present to each specialty (e.g. public health nursing, physical therapy, dental health, etc.) for assessment. At the end of each clinic, members of the ¡Salud! program conduct an interactive educational session on a spectrum of topics (e.g. personal health, mental health, nutrition, and stretching techniques).

Musculoskeletal Health Care: Prevention, Assessment, Treatment, and Education

Physical therapists and graduate students in the physical therapy program perform musculoskeletal examination and functional fitness screening assessments, provide treatment (e.g. stretching, relaxation, and manual therapy) if needed, review/educate workers on proper body mechanics, and prescribe therapeutic exercise when indicated (Brumitt et al., 2011).

The delivery of orthopedic physical therapy services at the onsite clinics differs from delivery of care within a traditional clinical setting. First, the delivery of care is performed at the vineyard and at some locations the care is provided outside. Second, the ability to provide treatments or prescribe exercises is limited to the equipment and modalities that can be transported (e.g. treatment table, elastic bands, aspects of the workers’ environment), and prescribe therapeutic exercise when indicated (Brumitt et al., 2011).

Educational Opportunities for Future Health Care Providers

Educating physical therapy students involves a combination of didactic coursework and clinical instruction (American Physical Therapy Association, 2004). There is a growing recognition by physical therapy educators of the necessity of additional academic and experiential learning opportunities to develop professionalism and foster interprofessional understanding and collaboration (Kelly & Miller, 2008; Reynolds, 2005). The majority of a student’s interaction with patients and opportunities for interprofessional collaboration occur during clinical internships (Reynolds, 2009; Reynolds, 2005). Clinical internships provide the opportunity for academic and professional growth; however, there are limitations as to the total number of clinical competency opportunities (Reynolds, 2005; Reynolds (2005).
Interprofessional Skill Development for Physical Therapy Students Participating in ¡Salud!

Discussion

This case report details the benefits associated with interprofessional collaboration between organizations to deliver health care services to an underserved and/or uninsured population. Migrant workers, students, and health care providers benefit from interprofessional collaboration. To the best of our knowledge, the ¡Salud! program is unique in its scope and delivery of service. This model, supported by monies raised by the vineyards and volunteer service from university faculty and students, helps to provide care for those who would be otherwise unable to afford basic services. The delivery of care via the mobile clinics brings the health care professionals to the worker, eliminating the challenges associated with negotiating the US medical system.

Despite the awareness that the Latino migrant farmworker is at risk for injury and generally lacks access to appropriate medical care, there is much to be learned about improving the delivery of care. Preliminary evidence suggests workers are at risk for MSS or MSD (Brummitt et al., 2011; Meyers et al., 2001). Future research should prospectively assess benefits associated with pre-season injury prevention interventions, identify risk factors associated with injury, and assess MSS and MSD in workers after the harvest.

Currently, aside from the interprofessional course, physical therapy student participation in community service (e.g., ¡Salud!) is on a voluntary basis. As such, assessment of student learning has been limited to qualitative reports. Students have reported improved confidence performing musculoskeletal examinations and joint manipulation techniques. In addition, students have gained awareness of inequities in health care access. Hopefully, awareness of health care inequities will impact future clinicians to provide pro-bono services to underserved populations. A few former students of the program have volunteered time following graduation.

A goal of the physical therapy program is to evolve this practice management expectation into an interprofessional course requirement, allowing students to build on their coursework.

community service into a formal service learning experience. Structuring the service learning experience will include measurable learning objectives and require student reflection (e.g. HPSISS Service-learning – Student Survey, reflective writing on cultural competence) (Reynolds, 2009; Shinnamom, Gelmon, & Holland, 1999; Wong & Blissett, 2007).

Conclusion

The collaboration between community health nurses and a university physical therapy team has benefited migrant workers, student physical therapists, and has facilitated research. Migrant workers are now receiving musculoskeletal services that may either reduce risk of injury (education, body mechanics, flexibility programs) or improve symptoms associated with a MSS or MSD (manual therapy, therapeutic exercise prescription). Students benefit from additional opportunities to practice while supervised by university faculty. Collaborations between physical therapists and community health nurses have facilitated research in a population that has been underserved. Additional investigations are necessary to improve the delivery of care for this population and the experiential transformation associated with student volunteerism.
